A step towards virtualization and automation, a milestone to recognize and build upon!

The Software Excellence team has been working with the Ultrasound team to reduce the load on physical hardware and open up possibilities for greater automation, parallel executions, machines that can come up on demand, and much more (think unit tests run on separate machines, parallel executions of SCA...).

In this attempt, in phase 1, we tried to see if we could automate the simulator machines used to run the AST suite of tests.

As a proof of concept, we collaborated with teams to:

- Get an OS that can be installed on a virtual machine.
- Convert the OS into an ISO image.
- Install it on a virtual machine in the VM farm (within PGN) to iron out issues.
- Execute sanity tests from ULTAST.
- Post the result execution on the STP web triaging dashboard.

We ran “**PresetCensus**” and “**Sanity1**” tests, both of which succeeded.

In this flow, we witnessed a successful cycle of AST sanity-test execution that runs on a virtual machine and posts the outcome to the triaging dashboard for everyone to view/dissect.

Here are the results for the same -> <http://stpweb.btl.ms.philips.com/cgi-bin/TriageDashboard.plx...>

Many thanks to the people who helped us pull this off!

Amazing work, team! Thank you Subramanya Vellal, Dattatreya for sharing and many thanks to each of the teammates who helped think through the "art of possibility" with regards to how we could begin to have impact in this space. Developer efficiency and "steps to deliver" have come up as one of our greatest areas of feedback across R&D teams, so it is great to see how we can begin to take steps in having something which we can see so clearly.
